

Interactive comment on “An intercomparison of mesoscale models at simple sites for wind energy applications” by Bjarke Tobias Olsen et al.

Anonymous Referee #2

Received and published: 23 January 2017

The manuscript provides a comparison of 25 atmospheric forecasts with mast observations for three different locations with a focus on wind energy related parameters. While the undertaking itself is very important for the wind energy community given the collected data especially from multiple commercial sources. In my opinion, however, there are several issues that need to be addressed before publication.

In general, the language of the manuscript needs some improvement. I gave several corrections in my detailed comments but I suggest a native speaker or a professional editing service to correct all of the numerous (small) errors. Further, I recommend to use present tense instead of past tense for most of the manuscript.

The section "Introduction" is too long and needs to be much more concise. Often, the authors do not only cite the essence of a referenced paper, but also provide additional

C1

detail about it which does not add value to the actual message. An example for this can be found on page 2 line 28ff: The authors cite Hahmann et al. (2014b) with an explanation on what was done in the study before adding the sentence "A year long wind climatology simulation was used as the test variable". This information is too detailed and can easily be omitted without lessening the message itself. Further, the introduction contains a lot of abbreviations. Some of these are even not used later in the manuscript, e.g. LCOE.

The use of the three comparison sites without measurements seems to be unnecessary. First, I would disagree that the data-less sites resemble the mast sites from a climatological perspective (e.g., wind climatology). Second, at horizontal resolutions down to 1km, comparable sites with a focus on near-surface PBL will be very hard to find. Third, the authors themselves do not provide much detail about the comparison. I suggest to omit this part of the comparison.

Most of my concerns with the manuscript are with the section "Individual model performance" which provides the results for the major objective of model intercomparison: The authors show that the models differ, but they fail to show why. In my opinion, in a comparison study of model simulations, the attribution of differences among the data sets with respect to the representation of the simulated parameters to the characteristics of the simulation systems is most important. While the authors list multiple such characteristics as potentially crucial to the quality of the simulations, e.g., model, physical process schemes, they fail to show a dependence of the single model results to these characteristics with the exception of showing the dependence of wind speed error to grid spacing in a very simplistic way. I think the reader as well as the quality of the manuscript would profit from more details, e.g., how do longer forecast lead times or smaller grid spacing reflect on the performance of the models presented in a plot similar to Figure 3.

I suggest to merge sections 4 and 5 into a "Conclusions"-Section which can contain a summary.

Page 18 Line 4: Please provide more detail: What is meant by "source of orography"?

Page 18 Line 7: I would expect that the model itself, initial boundary layer conditions and simulation time aka forecast lead time have a large impact on the model estimates. I wonder why the authors hypothesise that the impact of these factors will be of a lesser degree.

Page 18 Line 10: "... significant correlations were ..."

C4

Page 18 Line 18ff: When calculating correlations for wind speed over such distances (up to 500km), large correlation coefficients are to be expected given the data set used. A better approach would be to filter-out low frequency (e.g. days, weeks, months) variations in the time series in order to retrieve the intra-day wind speed variations. Then these can be used in an analysis to remove the obvious correlations between the mast sites.

Figures 3 to 9: Why is the MM variance plotted when every single MMi is shown in the diagram?

Figure 10: The dashed diagonal is misleading as it suggests that there is meaning to it which is not as far as I understand (Model resolution in km against wind speed bias in m/s). Please correct me if I am wrong.
